

**SEICHE 2022**

**Introduction to Arduino**

**Lesson 7– Grounding, ESD, Connecting LEDs**

**Instructor: Paul Frommeyer**

[www.paulfrommeyer.com](http://www.paulfrommeyer.com)

**Corporate Sponsor: DXC Technology**

# **REMEMBER!**

**Immediately copy the latest lesson folder (Lesson6 today) from your USB flash drive to your hard drive where you previously copied the other flash drive files (probably Documents folder)**

# Lesson Plan Overview

## Lesson 1 – Intro and Setup

[may require 2 classes]

- Introduction to class format
- Overview of lesson plan
- Presentation format (monitor, camera, screen, whiteboard)
- Inventory of Arduino kits
- Inventory of USB drives
- Installation of ESP32 serial port drivers (Windows only)
- Installation of Arduino software
- History of Computing

## Lesson 2 and 3 – Laptop operation review

- Control panel/Settings location
- Home directories and folder hierarchy
- Arduino file locations
- Search functions
- Open questions and issues
- History of Computing redux

## Lesson 4 and 5 – IDE essentials

- The boards manager
- Setting board type
- Installing Libraries
- Loading example sketches
- Finding and selecting the Arduino USB port
- Uploading a sketch to the microcontroller [Example Sketch#1]
- Basic Arduino sketch (program) structure
- Uploading your own sketch [Class Sketch #2]
- History of Telecommunications and Networking – Part 1

## Lesson 6 – DC Electricity Basics and DMM Intro

- Quick review: DC vs AC electric currents
- DC current operation
- Voltage vs Amperage (current)
- Ohm's Law
- Series vs parallel circuits
- Introduction to basic DMM functions and usage
- Measuring voltage [DMM usage #1]
- History of Telecommunications and Networking – Part 2

## Lesson 7 – Grounding, ESD, and Connecting LEDs

- Grounding
- The Phantom Menace of ESD
- Resistors!
- LED's [DMM usage #2, maybe]
- Powering LEDs – Ballast and dropping resistors
- Connecting LEDs to microcontrollers
- Parts of an Arduino Sketch
- ESP32 Specifications – Ampacity
- Let there be Light! – Class Sketch #2
- History of Telecommunications and Networking – Part 3

## Lesson 8 – ESP32 External power sources [may require 2 classes]

- Capacitors!
- Microcontroller board power requirements
- Board power input options and grounding
- Components with different voltage requirements – level shifting
- External power circuit design
- Connecting and using transistors
- Pulse width modulation and signal generation
- Connecting and using buzzers – Class Sketch #3

## Lesson 9 – Connecting smart LED strips

- Simplified serial communication protocols
- One-wire serial communication protocol
- Hardware vs software serial
- WS2812B and Neopixel connections – Class Sketch #4
- External device power design

## Lesson 11 – Connecting LCD and Matrix Displays

- The SPI serial protocol
- SPI connections – Class Sketch #5
- SPI device external power design

## Lesson 12 – Connecting sensors [Time permitting]

- Connecting buttons
- Connecting potentiometers and voltage dividers
- Reading buttons and debouncing
- Reading potentiometers

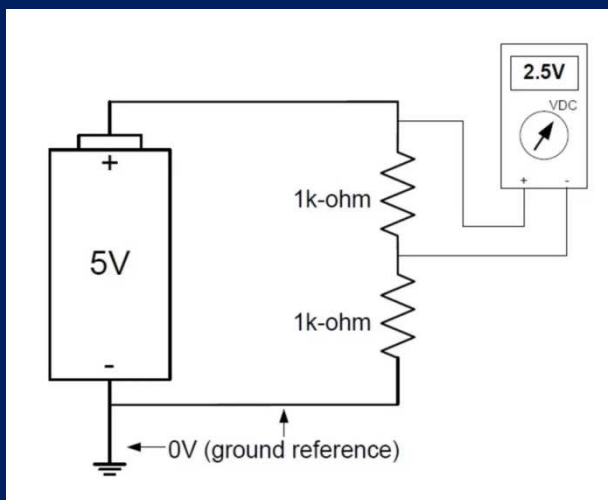

## Lesson 13 – Connecting more sensors [Time permitting]

- Connecting I2C sensors and photoresistors
- Using ESP32 integral touch sensors

# Lesson 7 – Connections

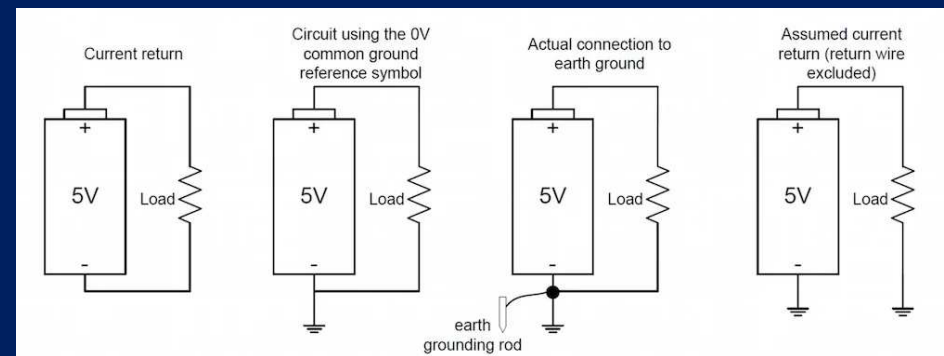

- Grounding
- ESD Safety
- Resistors
- LEDs
- Powering LEDs – Ballast and Dropping Resistors
- Connecting LEDs to Microcontrollers
- Parts of an Arduino Sketch
- WiFi Kit 32 Specifications Review - Ampacity
- Let There Be Light – Class Sketch #2
- History of Telecommunications and Networking P2  
(Time Permitting)

# Grounding – What is a Ground?

<https://www.allaboutcircuits.com/technical-articles/an-introduction-to-ground/>

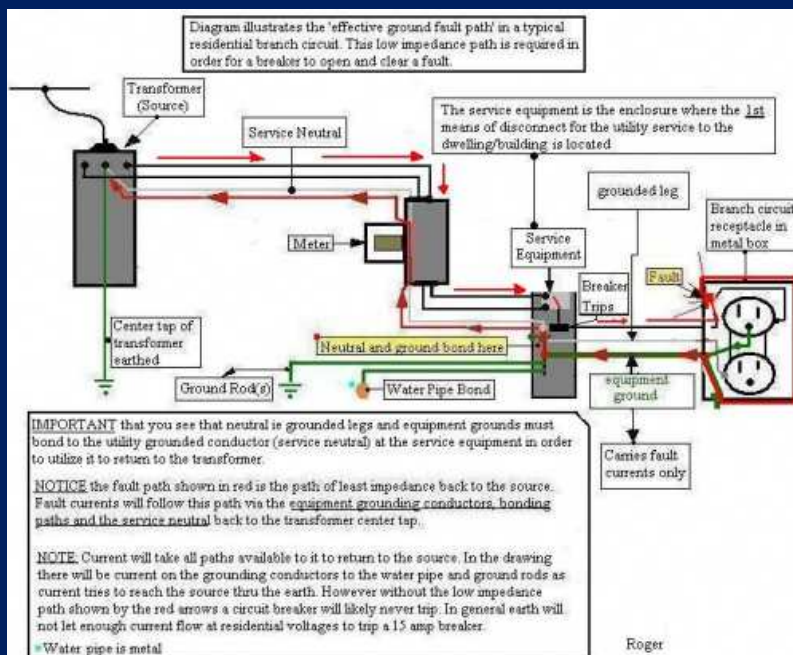

In electronics and electrical engineering, it is by convention we define a point in a circuit as a reference point. This reference point is known as ground (or GND) and carries a voltage of 0V. **Voltage measurements are relative measurements.** That is, a voltage measurement must be compared to another point in the circuit. If it is not, the measurement is meaningless. The ground reference point is often, but not always—more on this later—represented by a standard (earth) ground symbol.

# Grounding – Earth Ground

ground, general  
symbol /  
earth ground

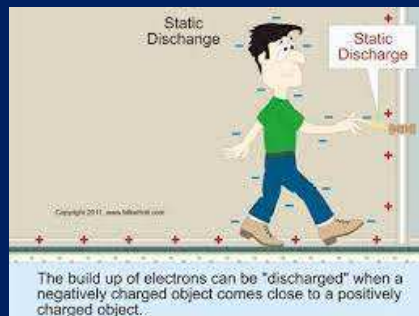

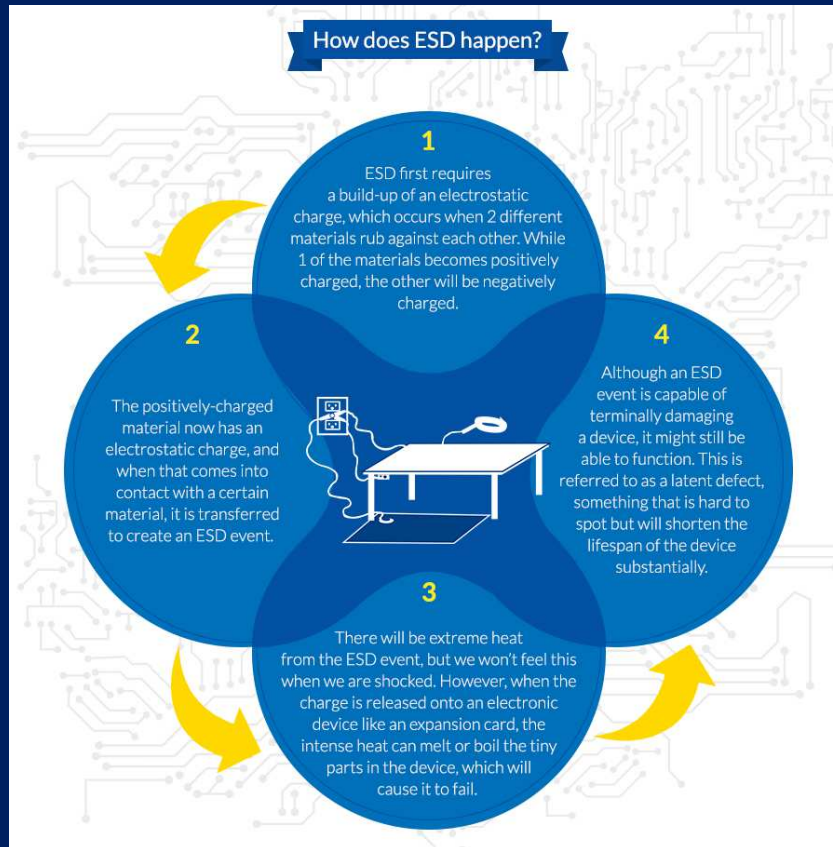

Earth ground is exactly as it sounds. It's a ground physically (and electrically) connected to earth via a conductive material such as copper, aluminum, or an aluminum alloy.

A true earth ground, as defined by the National Electrical Code (NEC), consists of a conductive pipe, or rod, physically driven into the earth to a minimum depth of 8 feet.

The earth provides an electrically neutral body, and due to the earth's virtually infinite state of neutrality, it is immune to electrical wavering. It should be noted, however, that "earth being immune to electrical wavering" is, in fact, a generalization. In reality, earth ground is quite the complex subject given all variables and materials that make up the earth. And, earth's electrical potential does indeed experience some isolated areas of varying due to events such as lightning hits, as an example. Power poles, those that are strung throughout neighborhoods, are also connected to ground.

# Electrostatic Discharge – The Phantom Menace

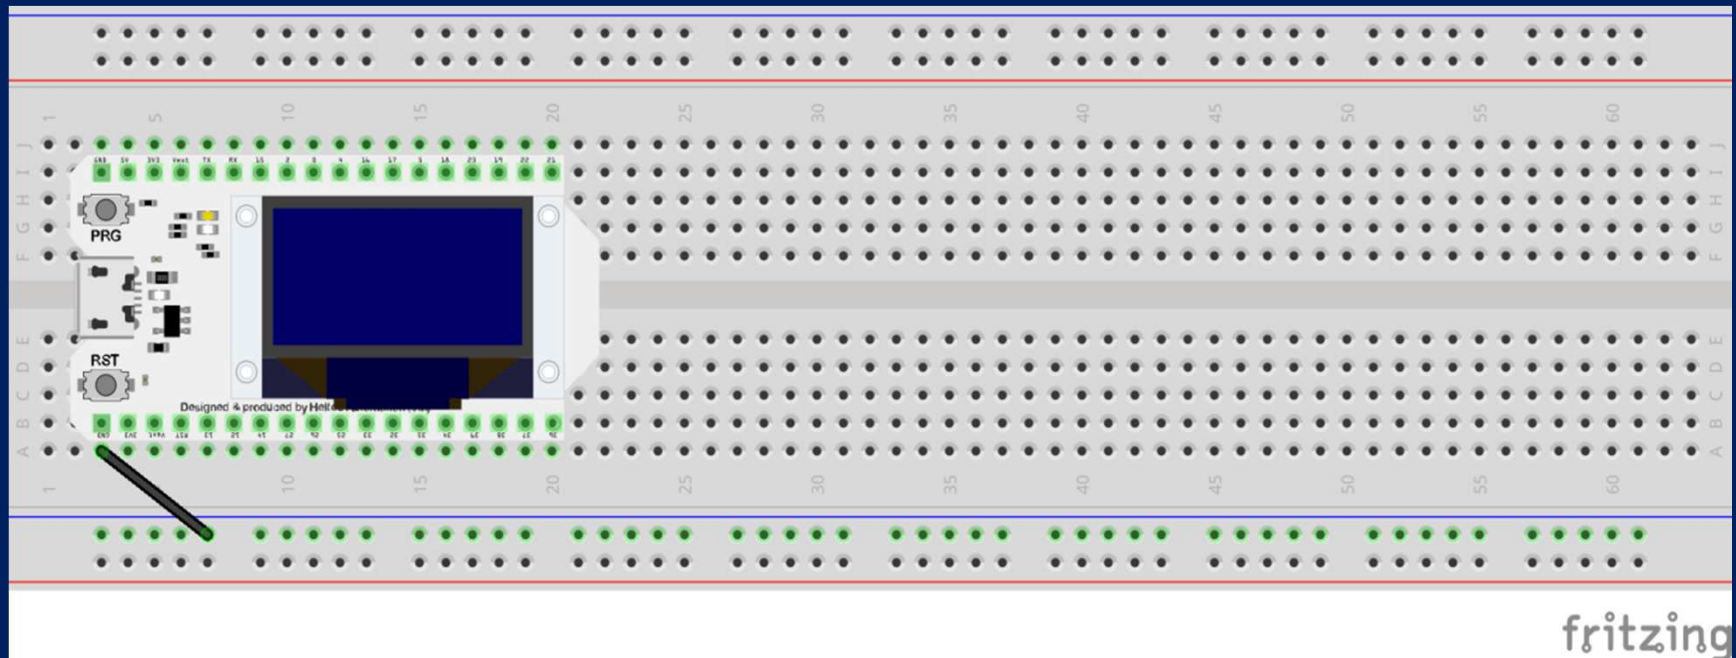

Integrated circuits (ICs) are notorious for being ultra vulnerable to ESD events. Grounded mats (referred to as ESD mats), grounded chairs, and wrist straps provide adequate ESD protection for your ICs by grounding you—thus discharging any static you may have on your body—prior to touching any sensitive components. Most engineers and technicians also wear ESD-safe jackets when working with PCBs and ICs for added protection against possibly damaging components and equipment.

**WiFi chips on dev boards are prone to static damage!!!**

# Electrostatic Discharge – Protection

Large charges need large grounds, but small charges only need small grounds. Metal the mass of a quarter is sufficient protection for most sensitive electronics, though earth ground is always best. The easiest place to find and attach such metal to a dev board is to just plug it into a breadboard. For particularly sensitive boards (which is us), it may be necessary to “permanently” connect the board ground to one or both of the ground busses on the breadboard. See diagram, above, for how to do this with the WiFi Dev Kit 32

Use the *bottom* blue rail for grounding, regardless of inside/outside

# Our First Component – Resistors!

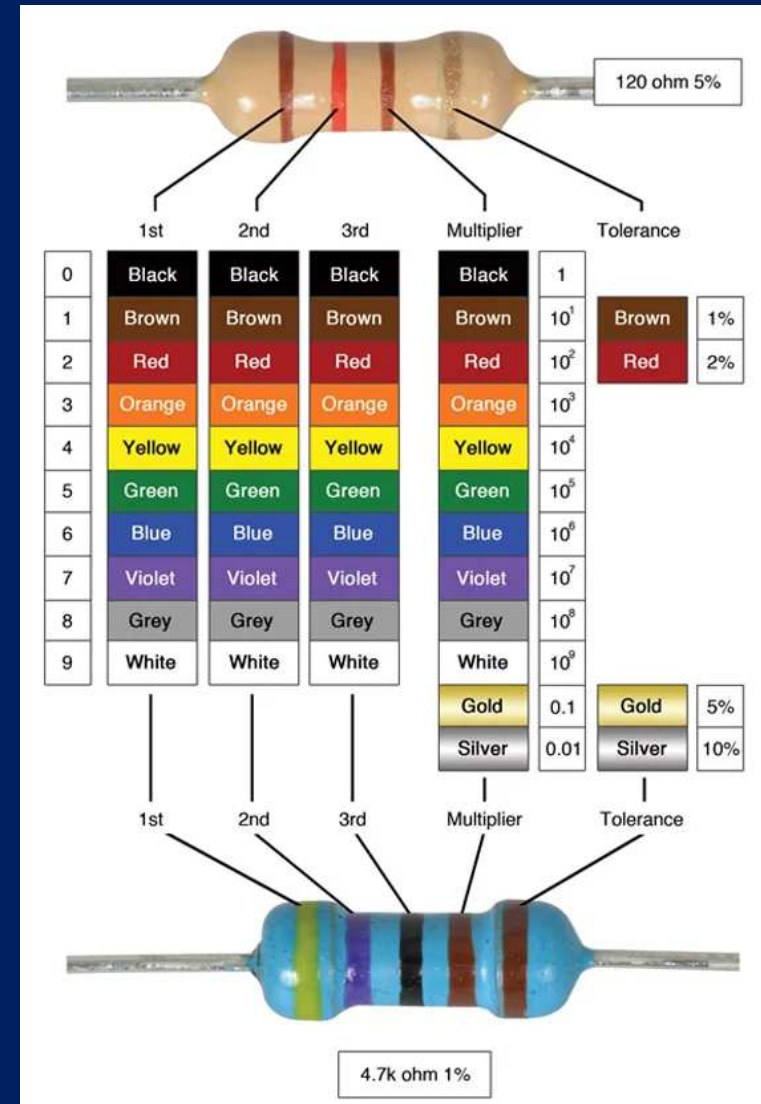

- Resistors are elements of electrical circuits that resist and reduce the flow of current through the electrical circuit. They can also be used to provide specific voltages to active components. Resistors are available with fixed or variable resistance values. Fixed resistors are ones in which resistance never changes.

[Mouser Electronics]

- A resistor is a passive two-terminal electrical component that implements electrical resistance as a circuit element. In electronic circuits, resistors are used to reduce current flow, adjust signal levels, to divide voltages, bias active elements, and terminate transmission lines, among other uses.

[Wikipedia]

- The function of a resistor is measured in Ohms of electrical resistance
- Resistors use a color code to indicate resistance and heat dissipation tolerance (wattage)
- When electricity passes through a resistor, the voltage of the current drops due to loss of energy. This is called voltage drop, and happens with nearly *all* components.

**Resistors are critical components, ubiquitous in electronic devices**

# Light Emitting Diodes

- LED – Light Emitting Diode
- A semiconductor component similar to a non-emitting diode or transistor
- Electrical current through the semiconductor chip produces light
- Semiconductor materials used define the color of light produced
- The “bluer” the light, the more energy (watts) the LED requires (consumes)
- Like all diodes, current can only flow one way through the component, even if its an LED, from + to -

## How Does an LED Work?

Electrical 4 U

**Shorter wavelengths have more energy, so require more energy to create the photons**

### Light, the visible spectrum

© 2012 Encyclopædia Britannica, Inc.

\* In terahertz (THz); 1 THz =  $1 \times 10^{12}$  cycles per second.  
 \*\* In nanometres (nm); 1 nm =  $1 \times 10^{-9}$  metre.  
 \*\*\* In electron volts (eV).

# Light Emitting Diodes

- Anodes (+ terminal) are usually connected to the microcontroller
- Cathodes (– terminal) are typically connected to ground
- LEDs are constant current devices, drawing between 10 and 20 mA depending on wavelength and emitter size
- To prevent burning out the microcontroller, limiting resistors are connected in series with the LED
- These “ballast” resistors can be connected to either the anode or cathode of the LED.
- It is best practice to connect a single resistor between the microcontroller GPIO pin and the LED anode
- There are h4x which ignore this (which we will do!)

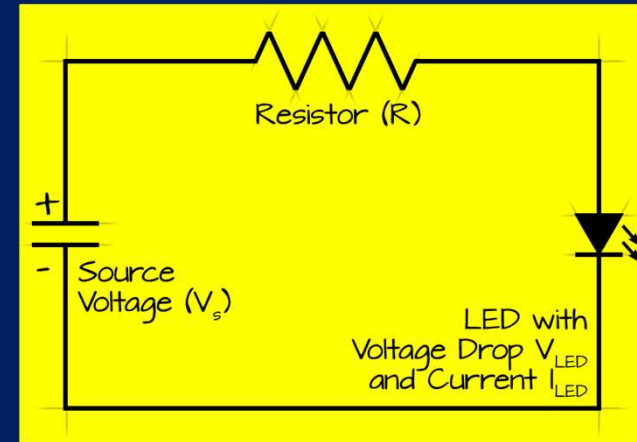

**Most microcontrollers have internal components for each GPIO pin called pull-up and pull-down resistors that are software controlled. We will study these as part of connecting buttons.**

# Ballast and Dropping Resistors

- A resistor can be used for current limitation. This resistor is called the ballast resistor. If the supplied voltage is equal to the LED voltage, a resistor will not be needed.
- If you are exceeding the LED voltage, you will need a resistor to resist the additional voltage. When calculating the resistor value, you will need to know the voltage drop across the LED first. An example would be a 12V power supply for a 2V LED. With the voltage drop of 2V, you can determine the additional voltage is 10V above the LED value. If the current in the circuit is 200mA, we can now use Ohm's Law to find the resistor value. With the additional 10V in the circuit and 200mA, the final result will be a 50 ohm resistor. Please note that the power rating for the resistor is important. Power can be calculated as  $V^2/R$ ,  $I^2 \times R$ , or  $V \times R$ . In this case, the absolute minimum power rating for this resistor can be 2W, but should be doubled for reliability at 4W.
- It's OK to use a slightly higher value resistor— in fact this is a good idea. Just be mindful of the resistor wattage.

**This is one of the most frequent times we use Ohm's law**

# Parts of an Arduino Sketch

- All sketches have two parts, or sections, of C++ code
- A setup section that runs once when the microcontroller is *powered up or reset* (note: not when the sketch is first loaded!)
- A loop section which runs continuously once the setup section has completed
- Technically speaking, these sections are individual *functions* and are called by a master function which the Arduino IDE elides (hides) from the user
- Setup is used to initialize variables, set pin operating modes, and other things to “set the stage” for the main program loop
- The loop is where the program steps (statements) for actual processing and events take place

# ESP32 Specifications

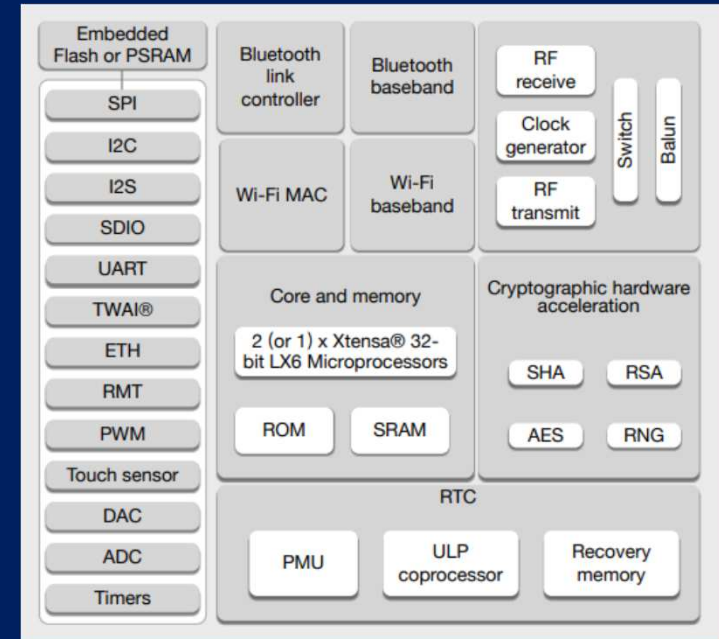

Table 15: DC Characteristics (3.3 V, 25 °C)

| Symbol               | Parameter  |  | Min                   | Typ | Max                   | Unit |
|----------------------|--|--|-----------------------|-----|-----------------------|------|
| C <sub>IN</sub>      | Pin capacitance  |  | -                     | 2   | -                     | pF   |
| V <sub>IH</sub>      | High-level input voltage   |  | 0.75×VDD <sup>1</sup> | -   | VDD <sup>1</sup> +0.3 | V    |
| V <sub>IL</sub>      | Low-level input voltage  |  | -0.3                  | -   | 0.25×VDD <sup>1</sup> | V    |
| I <sub>IH</sub>      | High-level input current   |  | -                     | -   | 50                    | nA   |
| I <sub>IL</sub>      | Low-level input current  |  | -                     | -   | 50                    | nA   |
| V <sub>OH</sub>      | High-level output voltage  |  | 0.8×VDD <sup>1</sup>  | -   | -                     | V    |
| V <sub>OL</sub>      | Low-level output voltage   |  | -                     | -   | 0.1×VDD <sup>1</sup>  | V    |
| I <sub>OH</sub>      | High-level source current<br>(VDD <sup>1</sup> = 3.3 V,<br>V <sub>OH</sub> ≥ 2.64 V,<br>output drive strength set<br>to the maximum) | VDD3P3_CPU<br>power domain <sup>1, 2</sup> | -                     | 40  | -                     | mA   |
|                      |  | VDD3P3_RTC<br>power domain <sup>1, 2</sup> | -                     | 40  | -                     | mA   |
|                      |  | VDD_SDIO power<br>domain <sup>1, 3</sup>   | -                     | 20  | -                     | mA   |
| I <sub>OL</sub>      | Low-level sink current<br>(VDD <sup>1</sup> = 3.3 V, V <sub>OL</sub> = 0.495 V,<br>output drive strength set to the maximum)         |  | -                     | 28  | -                     | mA   |
| R <sub>PU</sub>      | Resistance of internal pull-up resistor  |  | -                     | 45  | -                     | kΩ   |
| R <sub>PD</sub>      | Resistance of internal pull-down resistor  |  | -                     | 45  | -                     | kΩ   |
| V <sub>IL_nRST</sub> | Low-level input voltage of CHIP_PU<br>to power off the chip  |  | -                     | -   | 0.6                   | V    |

**Notes:**

1. Please see Table IO\_MUX for IO's power domain. VDD is the I/O voltage for a particular power domain of pins.
2. For VDD3P3\_CPU and VDD3P3\_RTC power domain, per-pin current sourced in the same domain is gradually reduced from around 40 mA to around 29 mA,  $V_{OH} \geq 2.64$  V, as the number of current-source pins increases.
3. For VDD\_SDIO power domain, per-pin current sourced in the same domain is gradually reduced from around 30 mA to around 10 mA,  $V_{OH} \geq 2.64$  V, as the number of current-source pins increases.

## DC Characteristics

ESP32 Block Diagram

## Takeaways

- Max pin source current: 40mA
- Max pin sink current: 28ma
- Pull-up resistance: 45K $\Omega$
- Pull-down resistance: 45K $\Omega$

**All Data From Espressif Systems ESP32 Datasheet**

[https://www.espressif.com/sites/default/files/documentation/esp32\\_datasheet\\_en.pdf](https://www.espressif.com/sites/default/files/documentation/esp32_datasheet_en.pdf)

# Time to Get Wired

What we are going to do, electrically speaking:

- Connect a red LED anode to pin GPIO13 (physical pin 5)
- Connect a green LED anode to pin GPIO12 (physical pin 6)
- Connect a blue LED anode to pin GPIO14 (physical pin 7)
- Connect all LED cathodes to a rail
- Connect that rail to the ground pin of the board using a 300 ohm resistor; this places the resistor in series between all three LED cathodes and the power sink (power ground)

## Notes:

\*GPIO input only  
\*ADC preamplifier  
GPIOs are 3.3V tolerant only

300Ω resistor connects here

GPIO13

GPIO12

GPIO14

The asterisk on these GPIO pins means they are INPUT ONLY and cannot be used to *send* electricity to anything. They can sink (accept) 28mA of current, which is dangerously small for accepting current from LED cathodes

# Connect The Dots

From your Arduino kits:

- Select a red, a green, and a blue LED
- Select three male-male DuPont jumpers, red, green, and blue
- Select a single 330 ohm (probably “R” on the label band) resistor
- And get your breadboard out if it's not already

Then, wire your breadboard up to look like this:

# Let There Be Light

- Find the Arduino sketch in your Lesson 7 folder (which you copied from your USB drives, right?) named “ClassSketch2-BlinkDeluxe” and open it in the Arduino IDE
- Connect your board to your laptop using USB cable
- Remember to set your board type and port speed
- Upload the sketch! ➔
- Did it work? You’ve the luck of me Irish ancestors! 🇮🇪 🍀 😊
- It didn’t work? Now you can prove yourself worthy of your maker name and troubleshoot the problem! ⚡ 🔧 😓

What happens if you make the delay values bigger? Smaller?  
Can you adjust the sketch to perform a “chaser” display?

# History of Telecommunications Part 2

THE INTERNET AGE

Much like the industrial revolution, the Internet revolution has changed the way people live, shop, socialize and work, and the way companies operate. In the run-up to the 20th anniversary of the 9 August 1995 listing of Netscape's shares on Nasdaq, Mint lists the important landmarks in the evolution of the Internet as we know it today, with special emphasis on India.

## Local Area Networks (LANs) Wide Area Networks (WANs) Wireless LAN (WiFi) Cellular Voice Networks Cellular data networks The Internet - Overview

1958: The US establishes the Defense Advanced Research Projects Agency (DARPA) in response to the USSR's launch of Sputnik during the Cold War.

1961: Leonard Kleinrock at the Massachusetts Institute of Technology (MIT) publishes the first paper on packet-switching theory—a theory that comes into use later for sending data through the Web.

1962: JCR Licklider of the MIT proposes the concept of a "Galactic Network", similar in concept to today's Internet. Licklider is chosen to head DARPA's research efforts.

1965: Computers TX-2 in MIT and Q-32 at Caltech are connected via a telephone network. With the first wide-area computer network comes the realization that time-sharing works well, at least on a local telephone network (circuit switching), but through packet switching.

1967: Lawrence G. Roberts of MIT goes to DARPA, comes up with his plan for ARPANET, publishes it, MIT (1964-67), RAND Corp. (1962-65) and the National Physical Laboratory (UK), the UK (1964-67), all research in parallel about packet switching without the knowledge of each other's work.

1968: BBN Technologies wins a contract to build the first network switch. Bolt Beranek and Newman (BBN) was a group set up by former MIT professors and headed by Frank Heart.

1969: Four different nodes in different universities in California and Utah are connected—the University of Utah, the University of California at Santa Barbara, Stanford and the University of California, Los Angeles (UCLA). Charley Kline of UCLA sends the first ARPANET transmission to Bill Duvall of Stanford. He attempts to send "LOGB" but the system crashes before he can reach "G". Only "LO" reaches.

1970: Packet-switched network Mark II is built to serve the NPL in the UK. Developed by Donald Davies, a Welshman and a colleague of Alan Turing while at NPL in the late 1940s.

Graphic: Mohan Shukla/Mint

1972: First program devoted to electronic mail (email) is created by Ray Tomlinson at BBN. The concept of "name" destination is created. Network Control Protocol (NCP) is also introduced to allow computers to send and receive data.

1976: The Ethernet is developed by Robert M. Metcalfe. It's a way of connecting computers together in a local area network (LAN).

1978: Queen Elizabeth II sends an email from England greeting a new programming language developed by the British ministry of defence via Internet. Her username: HM22 (Her Majesty, Elizabeth II).

1979: Bell Labs develops UNIX (Unix-to-Unix Copy) and Xerox.

1981: The National Science Foundation (NSF) releases CSNET 51, allows computers to network without being connected to government networks.

1983: TCP/IP becomes the standard for Internet protocol. For this reason, 1 January 1983 is celebrated as the unofficial birthday of the Internet.

1984: The number of hosts crosses 1,000. MCI Communications creates T1 lines for faster transportation of information over the Internet.

1990: Advanced Network and Services (ANS) develops the T3 line for faster speeds.

- A hypertext system is created and implemented by Tim Berners-Lee while working for CERN (European Organization for Nuclear Research).
- Archie, the first search engine, is created at McGill University, Canada. Archie's developer Peter Deutsch insists it is short for "archive" and has nothing to do with the name, via Internet, which is quoted when two follow-up engines, Veronica and Vindex, are created.
- CERN releases the World Wide Web publicly on 6 August.

1991: The US gives the nod to commercial enterprises to take off on the Internet—the first time to be used for anything but research.

1992: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

1993: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

1994: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

1995: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

1996: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

1997: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

1998: Satyam Infoway becomes India's first private ISP.

1999: The first commercial Internet service, America Online (AOL), is launched. AOL's first commercial service, America Online (AOL), is launched.

2000: The dotcom bubble bursts, narrowly, on 10 March. The Nasdaq Composite index peaks at 5,048.62.

2001: BlackBerry releases the first Internet cellphone in the US—BlackBerry 5810—with "push email".

2003: The French ministry of culture bans the use of the word "intel" by government ministries, adopts the use of the more French sounding "intelligence".

2005: YouTube is launched.

2006: The number of Internet websites reaches more than 92 million.

2007: Sachin Bansal and Binay Bansal start Flipkart.

2008: Google index reaches one trillion URLs.

2010: The first tweet from space, astronaut T.J. Creamer tweets from aboard the International Space Station.

2011: The number of Internet users reaches two billion.

2012: Facebook files for an IPO. It also reaches one billion monthly active users (104 million on mobile).

2013: Amazon becomes the largest hosting location with 180,000 Web-facing computers.

2014: The number of Web servers surpasses one billion.

2015: A debate on network neutrality garners public attention after Airtel announced in December 2014 that it plans to levy additional charges for making voice calls from its network using services such as WhatsApp and Skype.

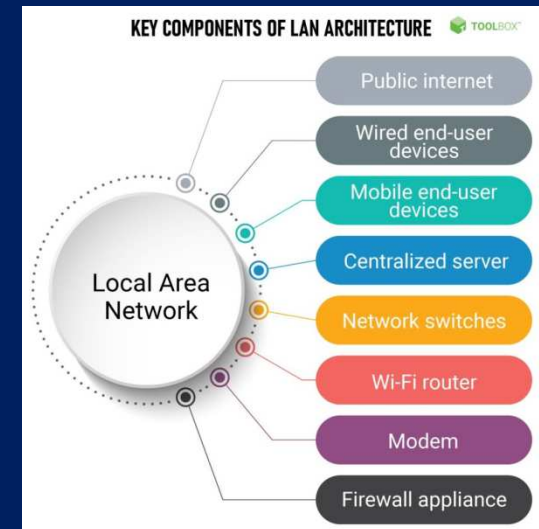

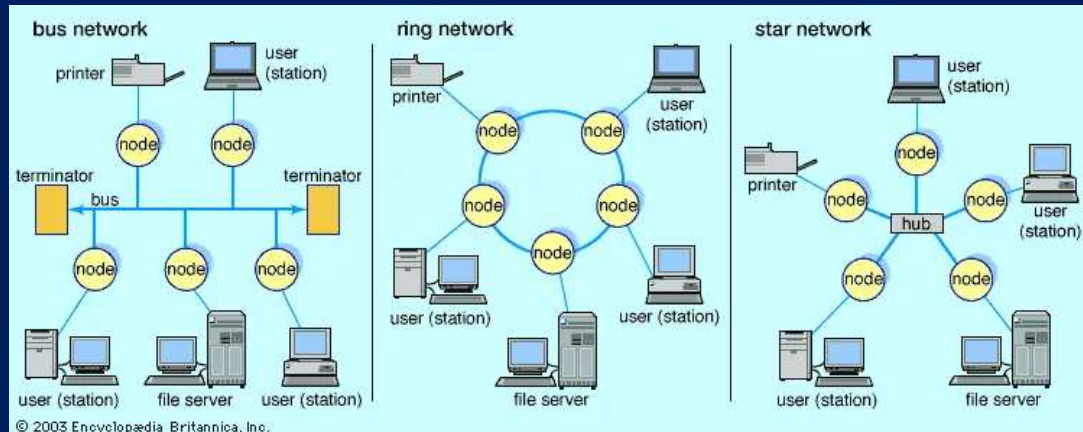

2016: A debate on network neutrality garners public attention after Airtel announced in December 2014 that it plans to levy additional charges for making voice calls from its network using services such as WhatsApp and Skype.

# Local Area Networks

- A local area network (LAN) is a group of computers and peripheral devices that share a common communications line or wireless link to a server within a distinct geographic area. A local area network may serve as few as two or three users in a home office or thousands of users in a corporation's central office.  
Source: TechTarget
- Regardless of size, a LAN's single defining characteristic is that it connects devices that are in a single, limited area. Source: Cisco Systems
- TL;DR a LAN is a group of computers in a single physical location connected together with physical cabling to allow exchange of data

# Wireless LAN (WiFi)

- WLAN/Wi-Fi is a family of wireless network protocols, based on the IEEE 802.11 family of standards, which are commonly used for local area networking of devices and Internet access, allowing nearby digital devices to exchange data by radio waves. These are the most widely used computer networks in the world, used globally in home and small office networks to link desktop and laptop computers, tablet computers, smartphones, smart TVs, printers, and smart speakers together and to a wireless router to connect them to the Internet, and in wireless access points in public places like coffee shops, hotels, libraries and airports to provide the public Internet access for mobile devices. Source: Wikipedia
- WLAN is the wireless technology used to connect computers, tablets, smartphones and other devices to the internet. Wi-Fi is the radio signal sent from a wireless router to a nearby device, which translates the signal into data you can see and use. Source: Verizon

## Types of wireless networks

|                 | Wireless LAN (WLAN)   | Wireless MAN (WMAN)   | Wireless PAN (WPAN)   | Wireless WAN (WWAN)                                 |
|-----------------|---|---|---|---|
| TYPE OF NETWORK | Local area network  | Metropolitan area network   | Personal area network   | Wide area network                                   |
| GOAL            | Provide internet access within a building or limited outdoor area | Provide access outside office and home networks, typically regional | Transmit signals between devices in limited areas, typically 100 meters | Provide access outside the range of WLANs and WMANs |
| CONNECTIVITY    | Cellular  | IEEE 802.16 WiMax   | Bluetooth, Zigbee and infrared  | LTE   |

# Cellular Voice Networks

- A cellular network or mobile network is a communication network where the link to and from end nodes is wireless. The network is distributed over land areas called "cells", each served by at least one fixed-location transceiver (typically three cell sites or base transceiver stations). These base stations provide the cell with the network coverage which can be used for transmission of voice, data, and other types of content. A cell typically uses a different set of frequencies from neighboring cells, to avoid interference and provide guaranteed service quality within each cell. When joined together, these cells provide radio coverage over a wide geographic area. Source: Wikipedia
- Cellular networks can be designed to carry voice, data, or both. The earliest cellular networks were voice networks, connecting back to the PSTN (Public Switched Telephone Network).

# Cellular Data Networks

- Cellular Network Data is a data connection from the cellular device to the cell site. LTE (4G), 3G and 1X are types of cellular network data connections. Data sessions include, but are not limited to, browsing the Internet such as Google, streaming music, videos and movies, sending and receiving emails, sending and receiving MMS messages, hotspot hosting and application use. While connected to the cellular data network, data usage will pull from the current data plan.
- As with all communications between two computers, “data” refers to information encoded into a bitstream of binary numbers. The method used for encoding varies by network layer, device, and communications protocol.

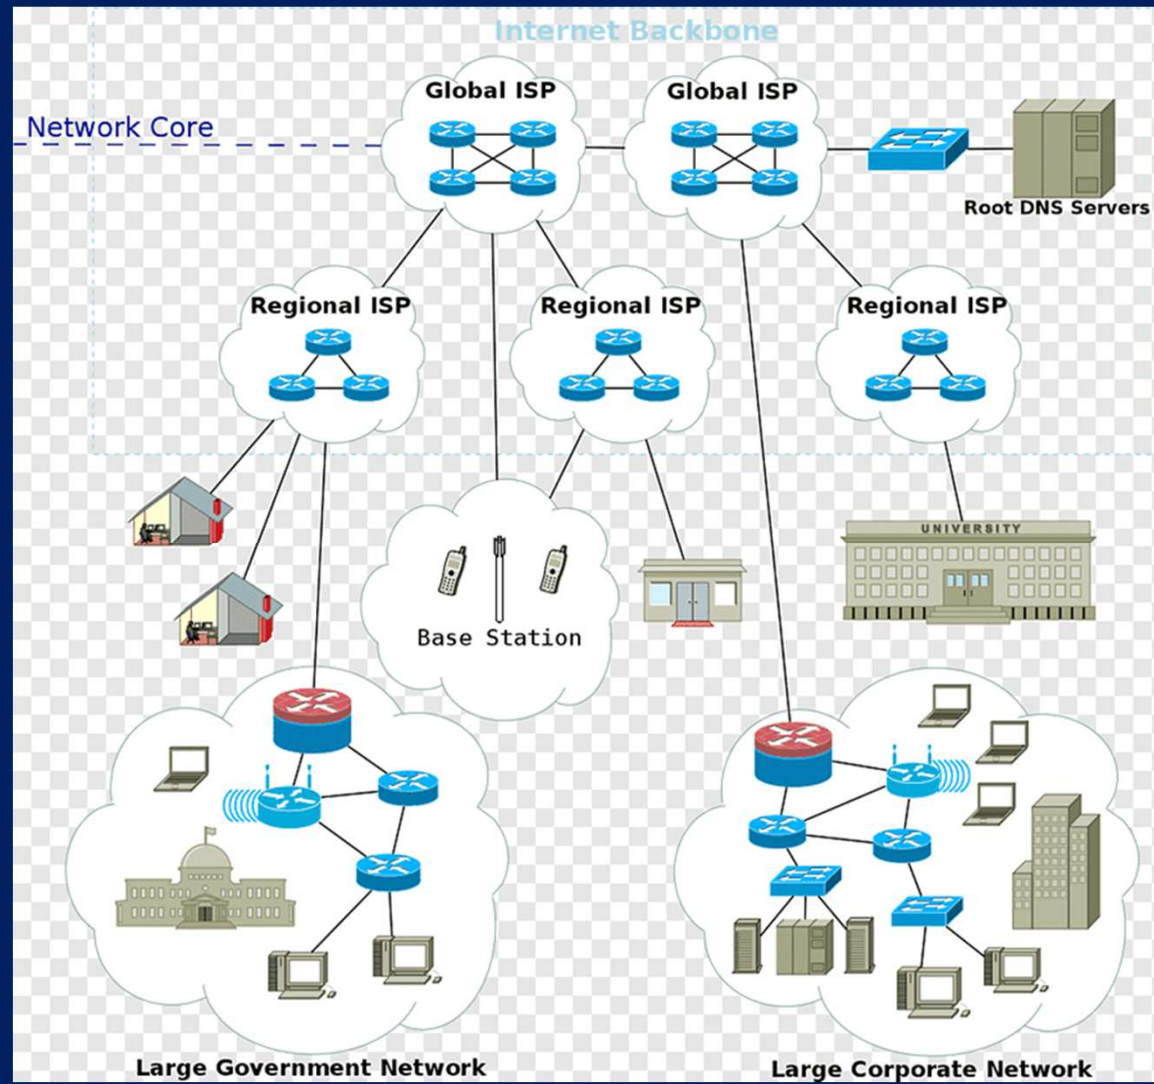

# WiFi and Cellular

- WiFi connects to a local router, cellular data connects to a remote router
- WiFi has a limited range, cellular data does not

# The Internet - Architecture

- The Internet is a “network of networks” used to connect many many LANs and WANs together
- Originally the Internet was owned and operated by the US DoD and NSF
- Public connectivity became available in 1992 from a company called PSI

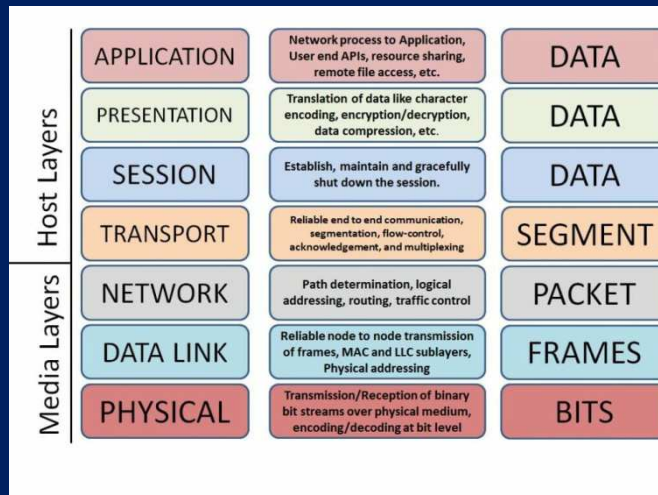

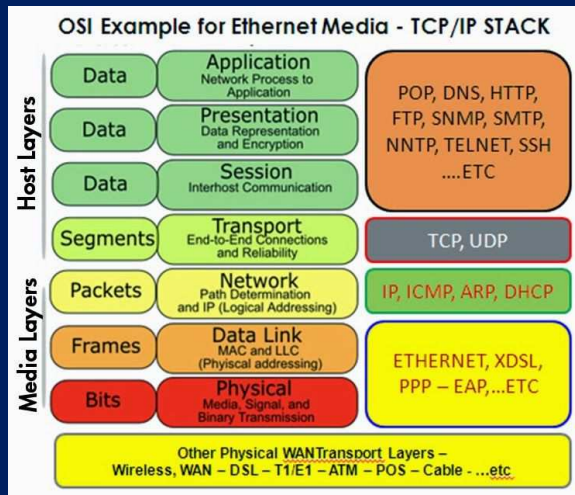

# The OSI/ISO Layered Network Model

- In a Quora post asking about the purpose of the OSI model, Vikram Kumar answered this way:
- “The purpose of the OSI reference model is to guide vendors and developers so the digital communication products and software programs they create will interoperate, and to facilitate clear comparisons among communications tools.”
- While some people may argue that the OSI model is obsolete (due to its conceptual nature) and less important than the four layers of the TCP/IP model, Kumar says that “it is difficult to read about networking technology today without seeing references to the OSI model and its layers, because the model’s structure helps to frame discussions of protocols and contrast various technologies.”
- If you can understand the OSI model and its layers, you can also then understand which protocols and devices can interoperate with each other when new technologies are developed and explained.

|              | Layer          | Protocol data unit (PDU) | Function <sup>[21]</sup>   |
|--------------|----------------|--------------------------|--|
| Host layers  | 7 Application  | Data                     | High-level APIs, including resource sharing, remote file access  |
|              | 6 Presentation |                          | Translation of data between a networking service and an application; including character encoding, data compression and encryption/decryption    |
|              | 5 Session      |                          | Managing communication sessions, i.e., continuous exchange of information in the form of multiple back-and-forth transmissions between two nodes |
|              | 4 Transport    | Segment, Datagram        | Reliable transmission of data segments between points on a network, including segmentation, acknowledgement and multiplexing                     |
| Media layers | 3 Network      | Packet                   | Structuring and managing a multi-node network, including addressing, routing and traffic control   |
|              | 2 Data link    | Frame                    | Reliable transmission of data frames between two nodes connected by a physical layer   |
|              | 1 Physical     | Bit, Symbol              | Transmission and reception of raw bit streams over a physical medium   |

# ISO/OSI vs The TCP/IP Model

- TCP/IP is the data interchange protocol used by the Internet for computer-to-computer (host-to-host) communications
- It only loosely follows the formal OSI/ISO reference model
- Many consider TCP/IP to be a separate model, but this is not entirely true
- We will not be studying TCP/IP in depth, but it is important to know that it exists and is the underlying protocol used in all web comms

**Accurate**

**Inaccurate**

# Formal End of Lesson 7

## In next week's exciting episode

- Microcontroller board power requirements
- Board power input options and grounding
- Components with different voltage requirements – level shifting
- External power circuit design
- Connecting and using transistors
- Pulse width modulation and signal generation
- Connecting and using buzzers – Class Sketch #3

***Don't forget to return your USB drives!***
